

Requirement Analysis Phase

Based on the provided project document, this section details the functional requirements, non-functional requirements, and client-side logic breakdown for the **Implement Client Script & UI Policy (Incident)** project.

1. Functional Requirements

- **FR1: High-Impact Trigger Condition**
 - When an Incident's Impact field is set to **1 – High**, specific field behaviors and validation rules must automatically apply.
- **FR2: Read-Only Urgency Control**
 - When Impact is **1 – High**, the Urgency field must automatically become **read-only** to prevent manual modification.
- **FR3: Automated Urgency Population**
 - When Impact is changed to **1 – High**, the system must automatically set the Urgency field value to **1 – High** and display an informational message to the user.
- **FR4: Conditional Mandatory Field Submission**
 - Prior to saving/submitting an Incident record, if Impact is **1 – High**, the Assigned To field must be populated. If it is empty, save execution must be canceled and an inline error message must highlight the Assigned To field.
- **FR5: List Edit Restriction on State**
 - Users must be restricted from modifying the State field directly within the Incident list view. A warning alert must be presented, and the field edit must be rejected. Form-based updates to State must remain allowed.
- **FR6: Reversibility**
 - If Impact is changed away from **1 – High** (e.g., to Medium or Low), field behavior restrictions (such as read-only on Urgency) must revert to their default states automatically.

2. Non-Functional Requirements

- **NFR1: User Experience & Instant Feedback**
 - Client-side validation and automated field updates must execute instantly on the user interface without requiring full-page reloads.
- **NFR2: Maintainability & Best Practices**
 - UI Policies must be prioritized over scripts for basic dynamic behavior (visibility, read-only, mandatory checks) to follow ServiceNow low-code best practices. Client scripts must only handle procedural logic (alerts, custom validation, list-edit callbacks).
- **NFR3: Data Quality & Consistency**
 - Prevent incomplete or invalid Incident submissions directly at the UI tier to ensure data integrity across the platform.

3. Solution Architecture & Technical Mapping

Requirement ID	Target Field	Trigger Event	Mechanism	Logic / Script Behavior
FR1, FR2, FR6	urgency	Impact = 1 - High	UI Policy & Policy Action	Sets urgency read-only = true; Reverse if false enabled.
FR3	urgency	impact field change	onChange Client Script	Calls g_form.setValue('urgency', '1') and g_form.addInfoMessage(...).
FR4	assigned_to	Form onSubmit event	onSubmit Client Script	Checks impact == '1' and assigned_to == ". Displays error box and returns false.
FR5	state	List view cell edit	onCellEdit Client Script	Alerts user and calls callback(false) to cancel list update.
